## Chapter Fifteen

# INTERCHANGE TYPE AND DESIGN STUDIES

Chapter 37 presents criteria for determining the warrants, application, and selection of various interchange types.

### 15-1 INTERCHANGE TYPE STUDIES AND ADDITIONS

The functional classification of the crossroad has a significant impact on whether an interchange is warranted and the type of interchange selected. In addition, traffic operations (e.g., freeway ramp terminal spacing, mainline weaving, level of service, signing) may affect the interchange type and spacing, especially in urban areas. The following sections present guidelines on the preparation and processing of Interchange Type Studies.

#### 15-1.01 Purpose of Interchange Type Studies (ITS)

Interchange Type Studies (ITS) are prepared to determine the preferred type, to aid in developing the design of the selected type, and to minimize the number of man-hours used before detailed design studies are initiated. When a corridor/design study is initiated for a new freeway or expressway, the Phase I project study group prepares a brief report that includes proposed interchange locations and describes the proposed interchange type at each location.

An existing freeway may require an additional interchange due to urban development or due to lack of proper access to an area, or an expressway may require the upgrading of an existing intersection to an interchange. In all cases, the proposal to provide an interchange must be justified and documented and may require an Interchange Type Study. Section 37-1 provides the guidelines for justification of need, and the results of the entire Study are documented in a report entitled *Request for Additional (Modified) Interstate (Freeway or Expressway) Access*.

As part of the access report, include the necessary information as discussed in Chapter 19 and in Part III, Environmental Procedures, that demonstrates the public benefits and need for an interchange (i.e., the "Purpose and Need"). See Chapter 35 for details on access control along the crossroad.

If the district determines that a conventional diamond or parclo Type C interchange is the most appropriate type of interchange at a particular location, an Interchange Type Study is not required. However, the district may prepare and submit an Interchange Type Study to BDE for review if assistance would be beneficial.

For complex interchanges, BDE involvement in type studies is recommended because of the larger number of alternatives requiring analysis and the typically higher costs. Complex interchange designs usually require more supporting information, such as:

- crossroad, ramp, and mainline profiles;
- access restrictions;
- weaving analyses;
- capacity analyses of entrance and exit terminals;
- lane balance;
- route continuity coordination;
- preliminary signing plans;
- topography;
- existing cultural developments; and
- cost estimates.

### 15-1.02 **Guidelines for Preparing Interchange Type Studies**

Use the following guidelines to prepare the Interchange Type Study:

1. **Base Exhibits.** Prepare a schematic drawing of the interchange layout on a print of an aerial mosaic or aerial mapping using a scale of 1 in = 400 ft (1:5000 metric) or 1 in = 600 ft (1:7500 metric). For complex interchanges, use a scale of 1 in = 200 ft (1:2500 metric) for rural areas and either a 1 in = 100 ft (1:1000 metric) or 1 in = 50 ft (1:500 metric) scale for urban areas. Figure 15-1.A illustrates a typical schematic drawing of an interchange layout. In addition, it is desirable to include a county map and a 0°7'30" quadrangle map as exhibits with the ITS. In urban areas, also include a city map showing the proposed interchange location(s).
2. **Alternatives.** When interchange type selection is controversial, prepare alternative schematics on separate aerial mosaics. Indicate which alternative is preferred and the rationale used in the selection.
3. **Content.** Schematic drawings may be prepared in the form of a single-line diagram. Show the layout of the mainline, crossroad, and ramps. Include the following information:
  - traffic flow diagram for projected DHV (e.g., typically based on 20 years);
  - functional classification, design speed, and design traffic volumes of both routes;
  - angle of intersection between mainline and crossroad;
  - angle of intersection between ramps and crossroad;
  - typical cross sections, including shoulder widths;
  - all existing and proposed radii of ramps and roadways;
  - lengths of left-turn lanes and taper rates;
  - limits of access control along the crossroad;
  - limits of ramps on the mainline and crossroad;

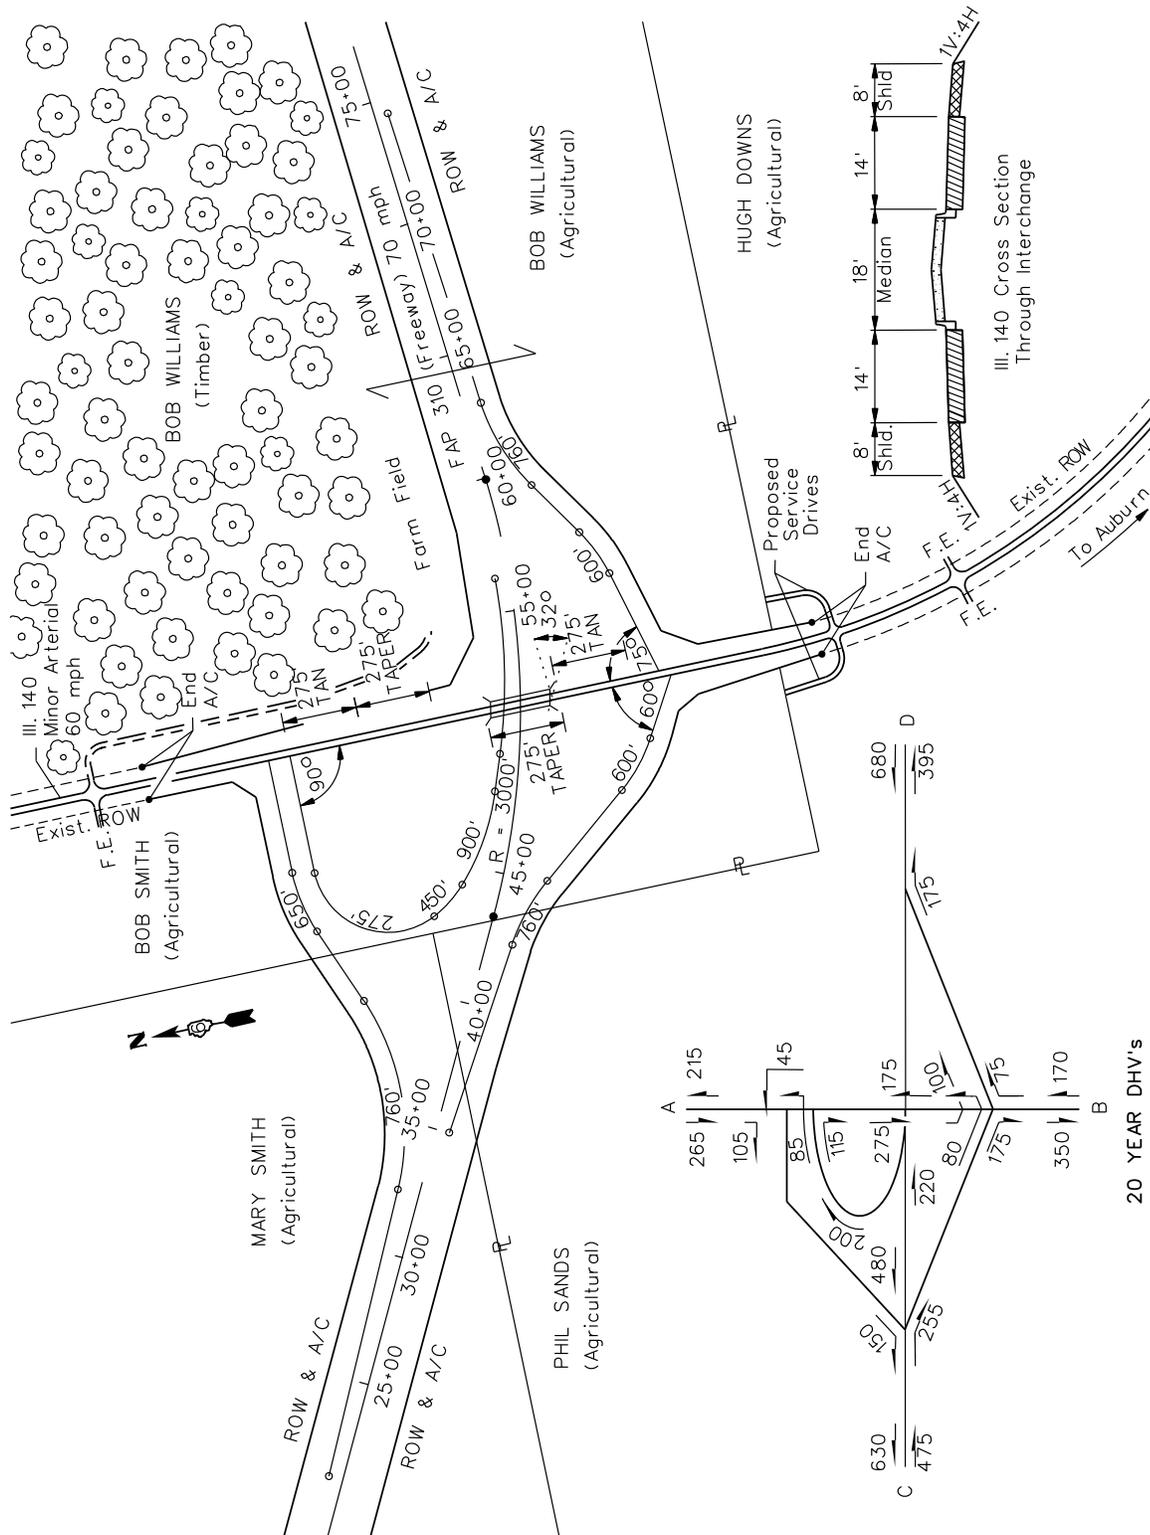

- any proposed structures;
  - any proposed local road relocation and frontage roads or service drives;
  - property lines and names of land owners; and
  - any relevant photographs of the area.
4. **Special Conditions.** List any special conditions (e.g., wetlands, historic site, archeological site) that support the development of an unusual interchange type, and include all necessary elements that control the design. Provide a statement regarding satisfactory alignments and profiles in conjunction with the design. If the development of preliminary profiles are necessary, include them with ITS.

### **15-1.03 Processing Interchange Type Studies**

The district is responsible for preparing the Interchange Type Study (ITS). Districts with a qualified Geometrics Engineer can approve the ITS.

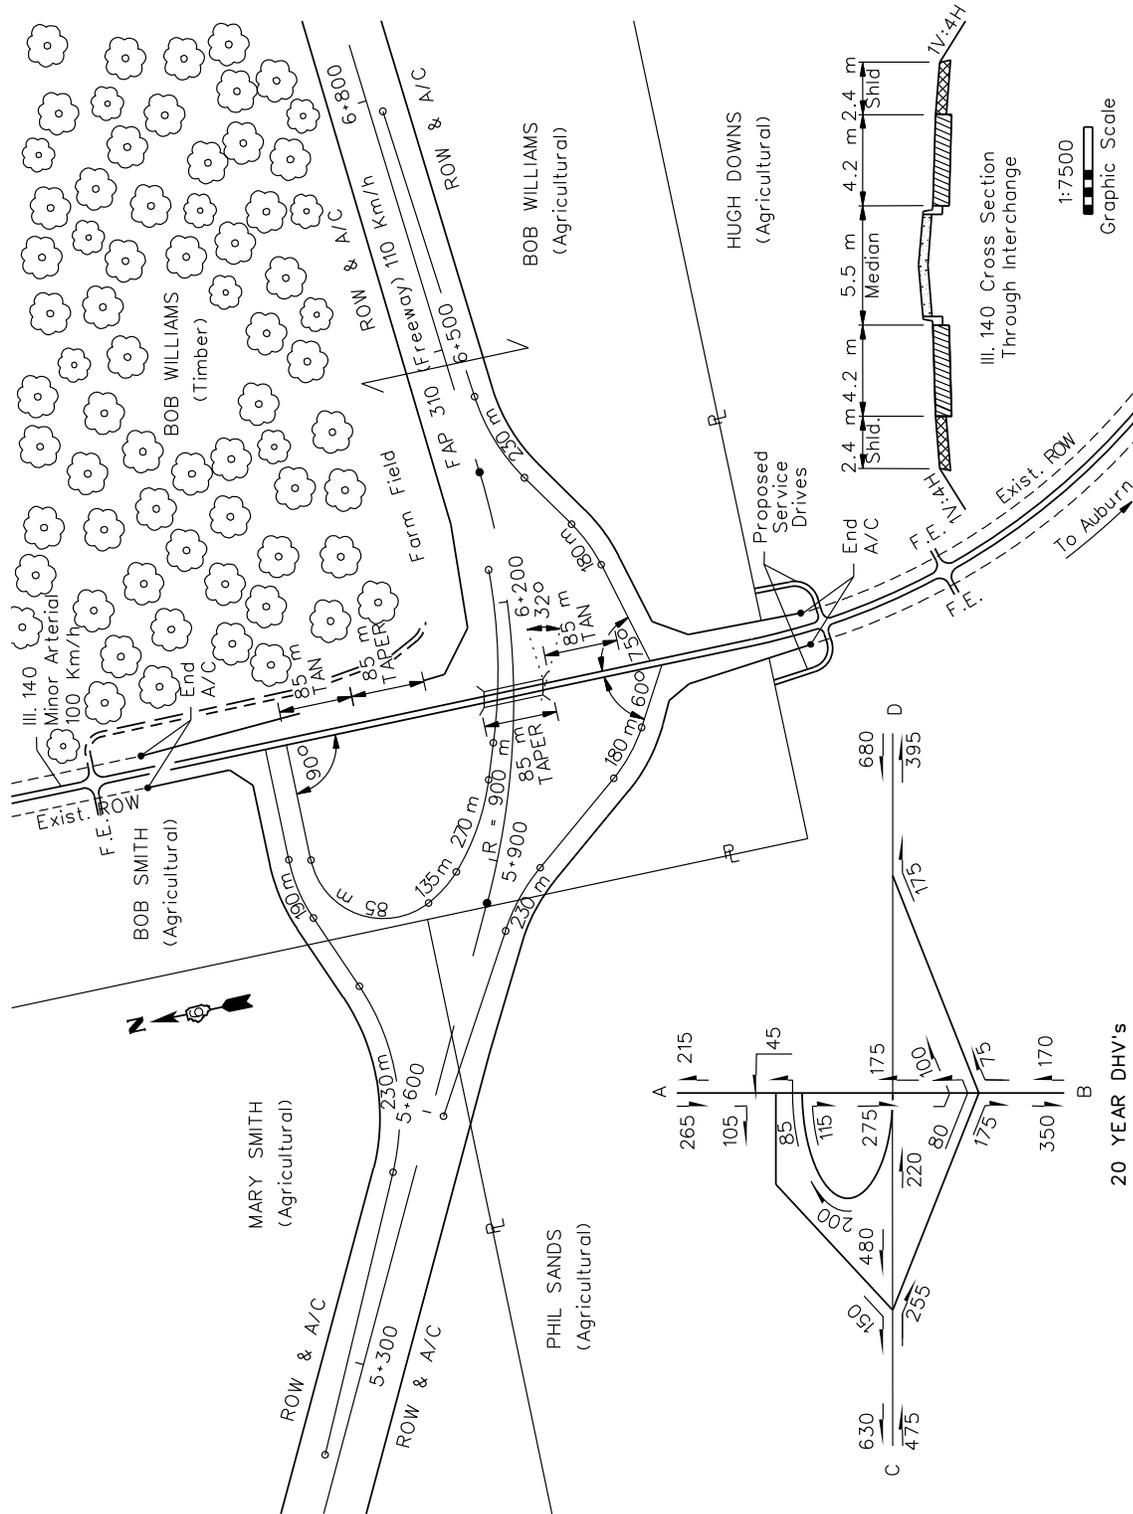

Access Justification Reports (AJRs) and access control changes on Interstates require coordination with headquarters. This is due to the complex nature of the designs and issues involved, and the need for statewide consistency. BDE will review and approve the documents for transmittal to FHWA for final Federal approval. If ITS is a part of access control modification and/or access justification report, the district should submit the report to BDE for review and approval.

Once the type study, interchange addition, or proposed change in access has been approved and, where necessary approved by FHWA, the district may initiate the preparation of the Interchange Design Study, as discussed in Section 15-2.

## 15-2 INTERCHANGE DESIGN STUDIES

Interchange Design Studies (IDS) are required for all interchange facilities. After the interchange type has been approved, preparation of IDS can be initiated. However, before design work is started, a field review should be made to each interchange location. The following sections discuss the guidelines and procedures for preparing IDS.

### 15-2.01 Guidelines for Preparing Interchange Design Studies

The IDS base sheets are standardized and available in the IDOT CADD cell library. These standardized sheet sizes along with formatting details are used in developing IDS. In general, prepare IDS in the same manner as an intersection design study; see Chapter 14 for format details. Figures 15-2.A, 15-2.B, 15-2.C, 15-2.D, and 15-2.E illustrate the typical format that should be used for uniformity on IDS plans. In addition, consider the following guidelines:

1. General.

- a. Drafting. The entire IDS is prepared on CADD. A controlled-scale aerial mosaic or aerial mapping usually is the base for development of IDS. This base is the visual description of the existing topography. Photographic inserts may be added for additional clarification.
- b. Scales. For interchange designs on new alignment, use topographic mapping at 1 in. = 200 ft (1:2500 metric) for the interchange layout. This scale allows the entire interchange to be shown on one sheet without match lines and also allows all property lines and roads to be shown around the interchange. If the interchange is being developed as a result of a planned upgrade of an existing route, usually an expressway design, use a scale ratio of either 1 in. = 100 ft (1:1000 metric) or 1 in. = 50 ft (1:500 metric). Also, for interchange designs in urban areas, the same scale ratios of either 1 in. = 100 ft (1:1000 metric) or 1 in. = 50 ft (1:500 metric) may be used. Larger scales aid in the decision-making process, especially where cultural land development or elevation restrictions are an issue.

2. First Sheet. Include the following information on the first sheet:

- a. Topography/Cultural Features. Include all houses, businesses, major utilities, roads and streets, right-of-way, access control lines, and structures on the topographic mapping. If contour lines are desired, plot them as light lines so they do not detract from the line work of the proposed interchange.
- b. General Notes. Include references to design exceptions, crash data, cultural development, terrain, improvement type, etc. See Section 14-3 for additional information.

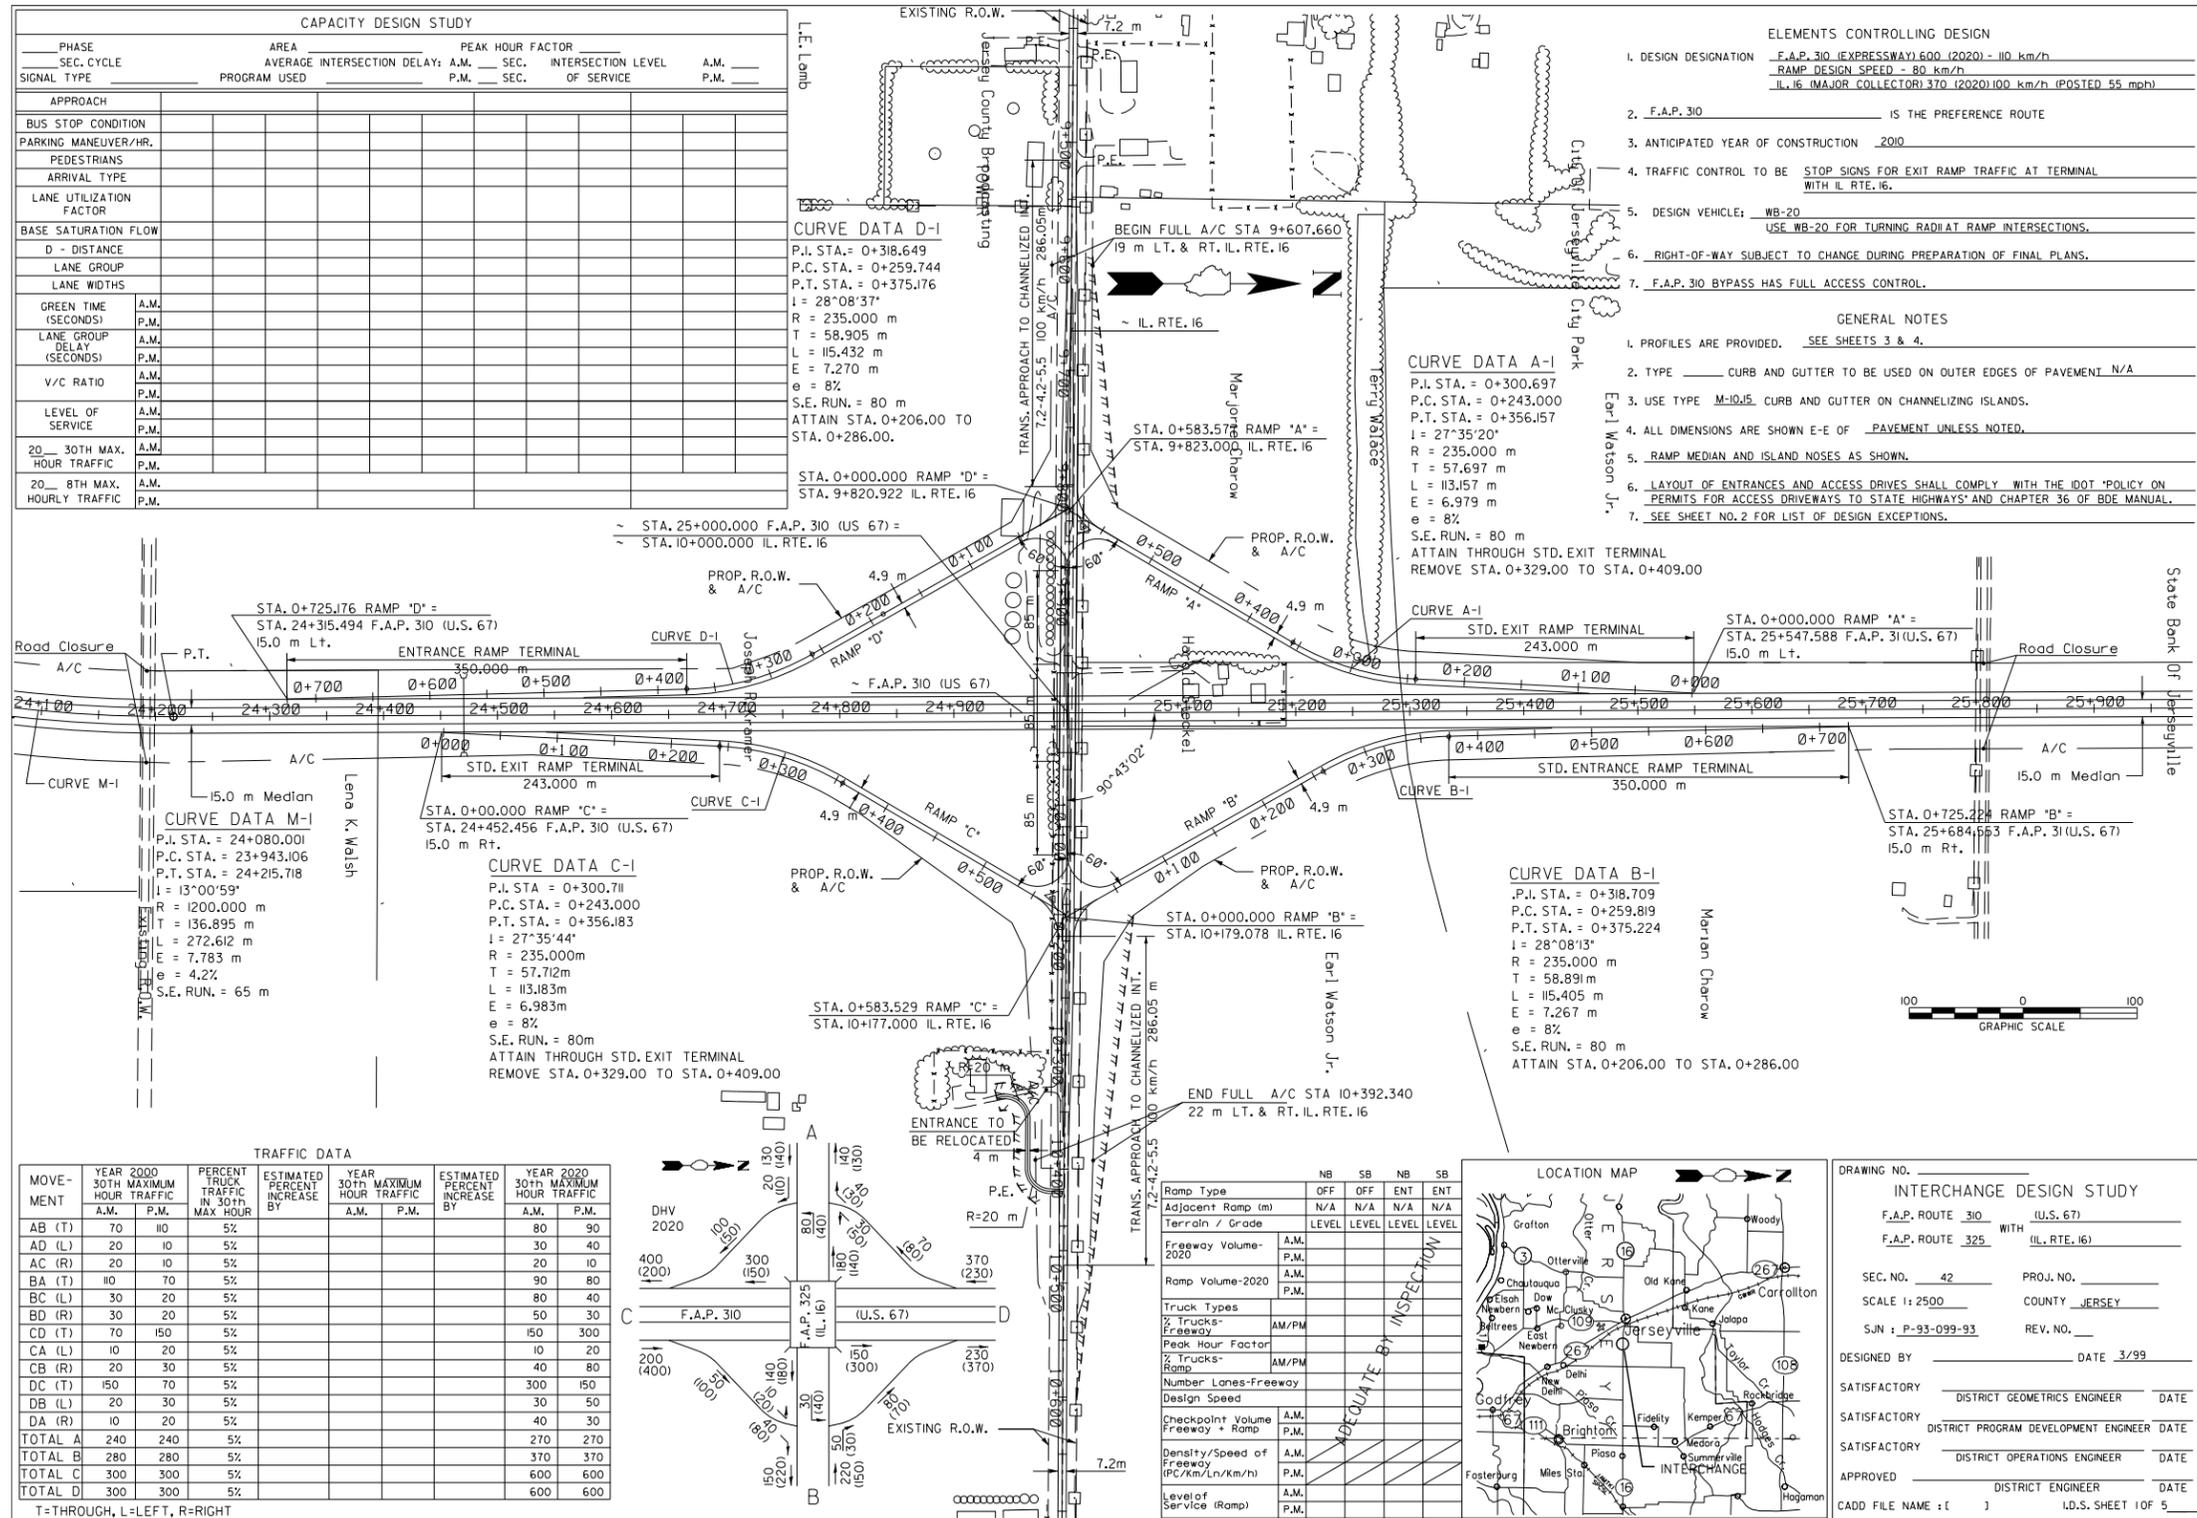

- c. Elements Controlling Design. Chapter 37 presents the design criteria for interchanges. On Sheet No. 1, list all pertinent elements affecting the design of the interchange.
  - d. Interchange Layout. Include horizontal alignment details, stationing, and proposed structures.
  - e. Capacity Analysis Table. For ramp/crossroad intersections, include the capacity analysis table in the upper left-hand corner. This table summarizes the results of the capacity analysis. See Chapter 14 for an example of the format.
3. Second Sheet. Show the details for each ramp/crossroad intersection, any specially designed free-flow terminals, and how the crossroad turn lanes are designed. If more space is needed, use an additional sheet for details. See Figure 15-2.B. Select a scale that will allow the details to be clearly shown. Include the capacity table for free-flow ramp terminals; see Figure 15-2.F. If weaving areas are proposed, also include a weaving analysis table as illustrated in Figure 15-2.G. This table should include a summary of the ramp capacity analysis and the number of lanes required.
  4. Profiles. After the crossroad details, show the profiles for the mainline and crossroad through the interchange; see Figure 15-2.C. Next, include the profiles for each ramp; see Figure 15-2.D. Where necessary, include detailed profiles for each turning roadway at the ramp crossroad intersections.
  5. Cross Sections. After the profile sheets, show all the necessary controlling cross sections adjacent to the mainline, a cross section for the mainline, if applicable, and a typical section of the ramp proper; see Figure 15-2.E. Figures in Chapter 37 indicate the locations where controlling ramp cross sections should be taken.
  6. Interchange Models. For very complex interchanges, it may be desirable or necessary to prepare a model for evaluating alternative interchange design features. This can be accomplished using a computer software package (i.e., GEOPAK) or by preparing a simple, three-dimensional model. The model may be developed by mounting the plan layout onto thin cardboard and then pasting the mainline, crossroad, and ramp profiles onto the plan sheet of the roadway alignment.

### **15-2.02 Processing Interchange Design Studies**

The Interchange Design Study (IDS) is prepared under the direction of and approved by the District Geometrics Engineer or BDE. Upon approval of IDS, the district will submit a completed BDE 2602 template to BDE for status information of IDS. The BDE will review and approve IDS if requested by the district or if the district does not have a qualified geometrics engineer. The procedure to qualify a District Geometrics Engineer is discussed in Section 11-9.

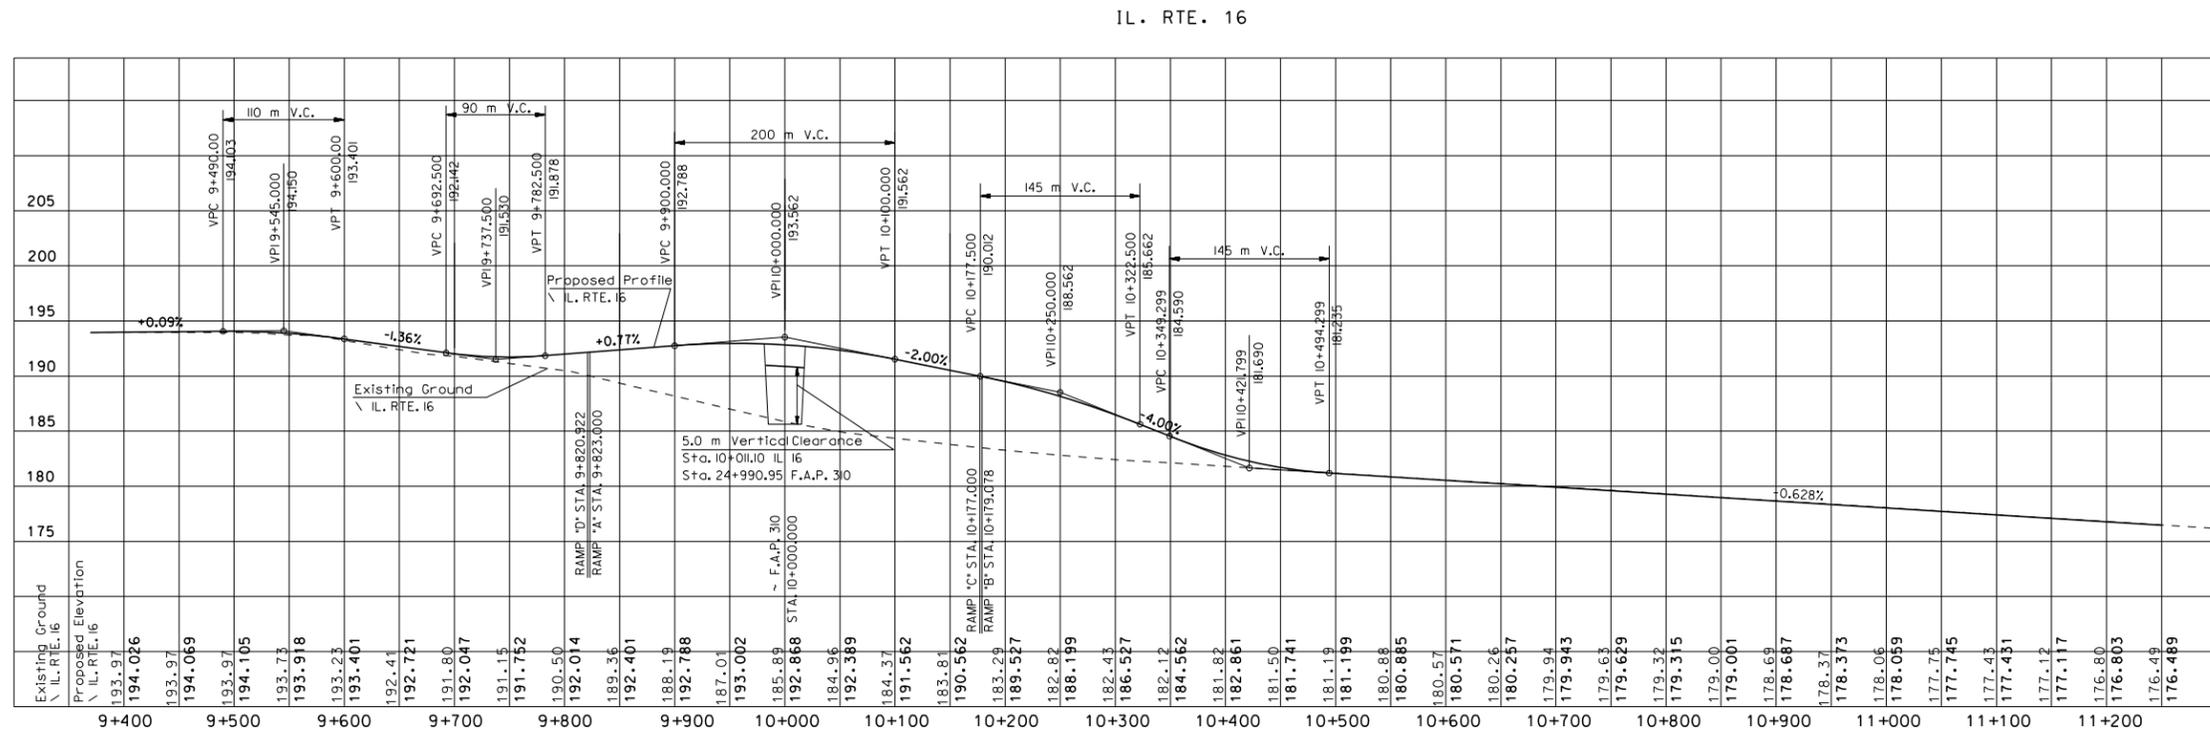

IDS on the Interstate system will require FHWA approval. IDS's used at public involvement activities should reflect the most recent design alternatives. Final approval of IDS is given with

design approval of the Phase I report. This final approval ensures that the social, economic, and environmental factors have been properly considered. Once the Phase I report has been approved, the IDS can then be used in the preparation of the detailed construction plans.
