WETLAND MITIGATION SITE MONITORING REPORT
FAP 310 (US 67) Mercer County

Introduction

This report details monitoring of the wetland mitigation site created to compensate for FAP 310 (US 67) in Mercer County. The site consists of approximately 0.69 ha (1.7 ac) of wetland creation (Site 1) and 0.28 ha (0.7 ac) of wetland restoration (Site 2). The wetland creation is located in the southeast quarter of the intersection of US Route 67 and the Edwards River; the restoration is located in the northeast quarter. The legal location is NE 1/4, SW 1/4, Section 35, T. 15 N., R. 2 W. The Illinois Department of Transportation (IDOT) completed construction of the site on 12 August 1997. Trees were planted during the fall of 1998 (T. Brooks, IDOT Wetlands Unit, memo to Allen Plocher, 10 February 1999). On-site monitoring was conducted on 9 September 1999.

This report discusses the goals, objectives, and performance criteria for the mitigation project, the methods used for monitoring the site, monitoring results, and a discussion and recommendations based on the results. Methods and results are discussed by performance criteria for each goal.

Goals, Objectives, and Performance Standards

Goals, objectives, and performance standards follow those specified in the monitoring plan (T. Brooks, IDOT Wetlands Unit, 1999) and the wetland compensation plan (C. Perino, IDOT Wetlands Unit, 1996) developed for this site. Performance criteria are based on those specified in the Corps of Engineers Wetlands Delineation Manual (Environmental Laboratory 1987) and in Guidelines for Developing Mitigation Proposals (USACE 1993). Each goal should be attained by the end of the 5-year monitoring period. Goals, objectives, and performance criteria are listed below.

Project goal 1: The created wetland community should be a jurisdictional wetland as defined by current federal standards.

Objective: The created wetland should compensate for the loss of 0.31 ha (0.76 ac) of floodplain forest and 0.09 ha (0.23 ac) of emergent wetland at a 1.5:1 ratio.

Performance criteria:
  a. Predominance of hydrophytic vegetation: More than 50% of the dominant plant species must be hydrophytic.
  b. Presence of wetland hydrology: The area must be either permanently or periodically inundated at average depths less than 2 m (6.6 ft) or have soils that are saturated to the surface for at least 12.5% of the growing season.
  c. Occurrence of hydric soils: Hydric soil characteristics should be present, or conditions favorable for hydric soil formation should persist at the site.

Project goal 2: The created wetland plant community should meet standards for floristic composition and vegetation cover.

Objectives: A floodplain forest will be created by planting native woody species. Herbaceous vegetation will be allowed to colonize the site naturally.
Performance criteria:
   a. Establishment of tree seedlings: Planted or volunteer tree seedlings should be
      established at each site.
   b. Floristic Quality Assessment: The floristic quality index (FQI) and mean coefficient
      of conservatism (c) for both sites should meet or exceed the FQI and c values of the filled
      wetlands, 7.0 and 2.0, respectively.
   c. Dominance of vegetation: None of the three most dominant plant species in either
      site may be non-native species, cattails (Typha sp.), or reed canary grass (Phalaris
      arundinacea).

Project goal 3: The created wetland should function to remove sediments from the
floodwaters of the Edwards River.

Objectives: The wetland creation site should retain floodwater and allow sediments to
settle out of suspension.

Performance criteria:
   a. Sediment removal: Sediments in the wetland should accumulate at a rate of 0.3 to
      1.1 in/yr.

Methods

Project goal 1
a. Predominance of hydrophytic vegetation
   The method for determining dominant vegetation at a wetland site is described in the Corps of
   Engineers Wetlands Delineation Manual (Environmental Laboratory 1987) and further
   explained in the Federal Manual for Identifying and Delineating Jurisdictional Wetlands
   (Federal Interagency Committee for Wetland Delineation 1989). It is based on aerial coverage
   estimates for individual plant species. Each of the dominant plant species is then assigned its
   wetland indicator status rating (Reed 1988). Any plant rated facultative or wetter, i.e., FAC,
   FAC+, FACW, and OBL, is considered a hydrophyte. A predominance of vegetation in the
   wetland plant community exists if more than 50% of the dominant species present are
   hydrophytic.

b. Presence of wetland hydrology
   Illinois State Geological Survey (ISGS) personnel installed seven ground water monitoring
   wells and one stage gauge at the site in 1999. Locations for these sites can be found in the
   ISGS report Edwards River/Mercer County Wetland Compensation Site (Miner 1999). Water-
   level data was collected monthly throughout the year and biweekly during April and May.
   Methods are further described in the ISGS document Annual Water-level Report for Active
   IDOT Sites (Fucciolo et al. 1999).

c. Occurrence of hydric soils
   The soil was sampled in order to monitor hydric soil development. Soil profile morphology
   including horizon color, texture, and structure was described at various points throughout the
   site. Additionally, the presence, type, size, and abundance of redoximorphic features were
   noted.

Hydric soils typically develop slowly, and characteristics may not be apparent during the first
several years after project construction. In the absence of hydric soils indicators at the end of
the five year monitoring period, hydrologic data could be used as corroborative evidence that
conditions favorable for hydric soil formation persist at the site.
Project goal 2

a. Establishment of tree seedlings
In order to create and restore floodplain forest, tree seedlings were planted at both compensation sites. According to the tasking order for this project (T. Brooks, IDOT Wetlands Unit, memo to Allen Plocher, 10 February 1999), the following number of trees were planted at the sites in Fall 1998:

<table>
<thead>
<tr>
<th>Species</th>
<th>Common Name</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acer rubrum</td>
<td>red maple</td>
<td>60</td>

</tr>
<tr>
<td>Quercus bicolor</td>
<td>swamp white oak</td>
<td>25</td>
</tr>
<tr>
<td>Quercus palustris</td>
<td>pin oak</td>
<td>25</td>
</tr>
</tbody>
</table>

Survivorship and density of planted trees was determined through quantitative quadrat sampling for the created wetland and by censusing for the restored wetland. In the created wetland, a baseline was established along the north edge. The baseline was divided into five segments of equal length and within each a random numbers table was used to select a starting point for a transect. Each transect extended perpendicular to the baseline across the width of the site. Along each transect, trees were sampled in 10 m x 10 m quadrats (32 ft x 32 ft) at regular predetermined intervals (20 ft and 100 ft). A total of 10 quadrats were sampled. Live planted trees within each quadrat were counted. The number of volunteer seedlings per plot was designated as occasional (less than or equal to 10) or abundant (greater than 10). Approximately 14.5% of the total area of the created wetland was sampled within the quadrats. All live trees at the restored site were counted.

Density of live planted trees is given as the number of live planted trees/100 m² for each site. Survival was calculated as a percentage of the number of expected live individuals: (Total number of live planted trees/the number of known planted trees) x 100. For the wetland creation site, the total number of live planted trees was estimated from the sample data.

b. Floristic Quality Assessment
The Floristic Quality Assessment (Taft et al. 1997) was applied to the plant community at the site to evaluate floristic quality and nativity. The assessment methodology is used to identify natural areas and facilitate floristic comparisons among sites. This technique is part of the procedure for the long-term monitoring of natural areas and the monitoring of restored or created wetlands (Swink and Wilhelm 1994). The premise of the method is that each native or adventive (but not introduced) plant species is assigned a conservatism coefficient (C) ranging from 0 to 10. Individual conservatism coefficients are ranks of species behavior and reflect the committee’s (Taft et al. 1997) confidence level for a taxon’s correspondence to anthropogenic disturbances. Coefficient values range from 0 to 10, with all adventive species given a coefficient of 0. Plant species assigned 0 have low affinities for natural areas, whereas those assigned 10 have very high affinities. When a complete species list is assembled for a wetland
site, the overall average conservatism coefficient (c) and a site floristic quality index (FQI) can be calculated. These values provide a measure of site floristic quality. Floristic quality index values (FQI values) less than 5 indicate that the area is extremely weedy or in an early successional stage (Swink and Wilhelm 1994). FQI values greater between 20 and 35 (c \geq 3.0) indicate that the area has evidence of native character and can be considered an botanical asset. FQI values between 35 and 50 (c \geq 3.5) indicate that the area has significant native character.

c. Dominance of vegetation
Plant species dominance was determined as in project goal 1, a. Predominance of hydrophytic vegetation. The method for determining dominant vegetation at a wetland site is described in the 

_Corps of Engineers Wetlands Delineation Manual_ (Environmental Laboratory 1987) and further explained in the 

_Federal Manual for Identifying and Delineating Jurisdictional Wetlands_

In addition, two permanent photography stations were established so that photographs could be used to document changes in plant community size and composition. The locations of the photo stations are indicated on the enclosed aerial photograph. Arrows indicate the direction in which the photos were taken.

**Project goal 3**
a. Sediment removal
ISGS personnel installed sediment traps in the wetland creation site in Fall 1999. No data has been collected from these traps at this time. Detailed methods will be included in the next annual report.

**Results**

**Project goal 1**
a. Predominance of hydrophytic vegetation
Dominant plant species for the mitigation sites in 1999 are shown in Table 3 and Table 4. All of the dominant species are rated OBL, FACW+, FAC+, or FAC and are, therefore, hydrophytic.

Table 3. Dominant plant species by stratum and wetland indicator status for the created wetland.

b. Presence of wetland hydrology
Ground water-level data for the created wetland for April through August 1999 is presented in Appendix A (Miner 1999). Ground water-level elevations are shown in Figure 1 and depth to water (referenced from land surface) is shown in Figure 2. Based on these data, none of the created wetland area satisfied wetland hydrology criteria in 1999 (Miner 1999). The interpretation of these results, however, is limited because surface-water levels on the Edwards River were not measured to date (Miner 1999). Surface-water levels will be measured beginning in Fall 1999. With this information, we will have a more complete picture of wetland hydrology at the site.

In addition, an outlet exists at the northwest corner of the site which allows water to flow from the site into the Edwards River. A memo from Tom Brooks to Allen Plocher accompanying the as-built plans, dated 3 May 1999, states that this outlet “should have recently been filled so that the created wetland is a shallow enclosed one.” However, at the time of this survey (9 September 1999), the outlet had not yet been filled. Blocking this outlet may be essential to establishing wetland hydrology at this site.

No monitoring wells were placed in the restored area and no indicators of wetland hydrology were observed. These indicators may not have been observed because this site has been disturbed within the last year by construction activities and tree plantings. The position of this site between the Edwards River and a levee, suggests that the area floods for some period of time each year. At this time, however, it is uncertain as to whether this site is inundated or saturated for a sufficient duration to satisfy the wetland hydrology criteria.

c. Occurrence of hydric soils
Soils examined at both of the mitigation sites were found to be highly disturbed. Much cutting and filling has been done within the top twenty inches and the sites lack a true undisturbed A horizon.

At the wetland creation site, gravel was found in the upper twenty inches confirming that a road bed once occurred on the site. Even though the soils are disturbed, hydric soil indicators are present. Following is a soil description of a typical pedon at the site.

Table 5. Description of the soils at the created wetland (Site 1).

</table>

In addition to being disturbed, soils at the restoration site are also compacted and contain much rock and gravel. Soils could not be penetrated more than a couple of inches and so a
thorough description was not done and no determination was made concerning the hydric nature of these soils.

Project goal 2
a. Establishment of tree seedlings
Tables 6 and 7 show the results of the sampling of trees at Site 1 and the censusing of trees at Site 2, respectively. Both volunteer and planted tree seedlings are becoming established at the sites. At the created wetland, a total of 33 trees were counted within the sampled quadrats for a mean density of 3.3 live planted trees/100 m². The total number of live planted trees at the site was estimated to be 228 with an estimated survival rate of 95%. The number of live planted trees per plot ranged from 0 to 5. All but two of the sampled plots had at least one live planted tree. Volunteer tree seedlings were observed in 50% of the sampled plots. No Acer rubrum trees were found within the plots or observed at Site 1. It is possible that these trees were never planted at the site.

A total of 57 live planted trees were present at Site 2 for a survival rate of 57% and density of 2.0 live planted trees/100 m². Volunteer seedlings of Acer saccharinum and Populus deltoides were occasional throughout the site.

Density: 2.04 trees/100m²
Total: 57 trees for this 0.28 hectare area (57% survival)
Occasional volunteer tree seedlings were present throughout the area.
b. **Floristic Quality Assessment**
Two FQI values were calculated for each site from the species lists included in Appendix B. The first FQI value is calculated from only species which became established on the site naturally; the second FQI value includes the planted trees. The created wetland has an FQI value of 9.3 and ac of 1.6 when only natural vegetation is included. When the planted trees are added, the FQI value is raised to 11.3 with a $\bar{c}$ value of 1.9. The FQI value for the restored wetland is 7.9 with a $\bar{c}$ value of 1.5 when only naturally established vegetation is considered, and 11.0 and 1.9 when the planted trees are included. In all cases, the FQI value exceeds the requirement of 7.0, however, in all cases, the $\bar{c}$ value is lower than the required 2.0.

do. **Dominance of vegetation**
Both mitigation sites meet the performance criteria for dominance of vegetation. None of the three most dominant species at either site are non-native species, cattails, or reed canary grass. All of the dominant species (Table 3 and Table 4) for both sites are native except *Setaria glauca*. This species, although common, is not one of the three most dominant species at either site. *Ambrosia trifida* and *Panicum dichotomiflorum* are among the three most dominant species at the restoration site. These are weedy undesirable species, however, like *Setaria glauca*, they are early successional shade-intolerant species and should disappear from the site as the trees grow and canopy cover increases. Cattails and reed canary grass occur at the created wetland site, but only in small numbers.

Photographs were taken from the permanent photography stations and are in Appendix C of this report.

**Project goal 3**
a. **Sediment removal**
No data has been collected from the sediment traps at this time. Results will be included in the next annual report.

**Discussion**

After one monitoring season, these sites show progress towards floodplain forest establishment. With slight modifications to improve wetland hydrology, the sites will most likely comply with project goals, objectives, and performance standards by the end of the monitoring period.

The vegetation at both sites is hydrophytic and meets the dominance criteria for native non-invasive species. Both volunteer and planted tree seedlings are becoming established on the sites. The FQI values are above the required level, however the $\bar{c}$ values are low. This means that there are a large number of species at each site that have very low coefficients of conservatism (C). This is common on disturbed and early successional sites and is not a cause for concern at this time. It is likely that as succession progresses, more conservative species will become established on the site.

The primary concern at this time for these sites is establishing (or finding evidence of) wetland hydrology. For the created wetland, filling in the outlet in the northwest corner may be a simple solution to this problem. Also, by monitoring the surface-water levels of the Edwards River, it may be shown that wetland hydrology already exists on the site. For the restored wetland, observing the site again in a year when it has more time to recover from recent disturbances, may reveal that it does indeed have wetland hydrology.
Soils at both sites have been seriously disturbed. Even so, the soils at the created wetland site do contain some hydric soil indicators, and therefore can be characterized as hydric. Soils at the wetland restoration site are very compacted and contain much gravel and rock. This may be a detriment to the establishment and survival of vegetation at the site. Herbaceous vegetation at the site was much more sparse than at the created wetland. It may also impede the development of hydric soils at the site. Water will not be able to readily penetrate the site and will run off more quickly.

ROUTINE ONSITE WETLAND DETERMINATION
Site 1 (page 1 of 5)

Field Investigators: Feist, Keene, Larimore, Wilm
Date: 9 September 1999 Project Name: FAP 310 (US 67)
Section No.: 104RS-2, (104)BR, (104-1)BR, 105RS-2
State: Illinois County: Mercer Applicant: IDOT District 4
Site Name: Wetland creation
Legal Description: NE 1/4, SW 1/4, Sec. 35, T. 15 N., R. 2 W
Location: This wetland creation site is located 38.1 m (125 ft) south of the Edwards River and 15.2 m (50 ft) east of US 67.

Do normal environmental conditions exist at this site? Yes: X No: 
Has the vegetation, soils, or hydrology been significantly disturbed? Yes: No: X

VEGETATION
Dominant Plant Species Indicator Status Stratum
1. Bidens cernua OBL herb
2. Echinocloa muricata OBL herb
3. Polygonum lapathifolium FACW+ herb
4. Polygonum pensylvanicum FACW+ herb
5. Setaria glauca FAC herb

Percentage of dominant species that are OBL, FACW, FAC+, or FAC: 100%

Hydrophytic vegetation: Yes: X No:
Rationale: More than 50% of the dominants are OBL, FACW, FAC+, or FAC.

SOILS
Series and phase: Undetermined
On Mercer County hydric soils list? Yes: No: X
Is the soil a histosol? Yes: No: X Histic epipedon present? Yes: No: X
Redox concentrations: Yes: X No: Redox depletions: Yes: No: X
Matrix color: 2.5Y 5/1
Other indicators: This soil is found in a level to depressional area.

Hydric soils: Yes: X No:
Rationale: This soil surface has been altered somewhat because of cut and fill activities associated with an old road bed. This soil meets the requirements of the Natural Resource Conservation Service hydric soil indicators F5 and F6, thick dark surface and redox dark surface, respectively.
ROUTINE ONSITE WETLAND DETERMINATION
Site 1 (page 2 of 5)

Field Investigators: Feist, Keene, Larimore, Wilm
Date: 9 September 1999        Project Name: FAP 310 (US 67)
Section No.: 104RS-2, (104)BR, (104-1)BR, 105RS-2
State: Illinois        County: Mercer        Applicant: IDOT District 4
Site Name: Wetland creation
Legal Description: NE 1/4, SW 1/4, Sec. 35, T. 15 N., R. 2 W
Location: This wetland creation site is located 38.1 m (125 ft) south of the Edwards River and 15.2 m (50 ft) east of US 67.

HYDROLOGY
Inundated: Yes: No: X        Depth of standing water: NA
Depth to saturated soil: > 1.2 m (48 in)
Overview of hydrological flow through the system: This site is hydrologically influenced by overflow from the Edwards River and by precipitation. Water leaves the site via evapotranspiration and sheet flow into the near by Edwards River.
Size of Watershed: 699 km² (270 mi²)
Other field evidence observed: Seven wells were placed at this site to monitor the water levels during the 1999 growing season. Water levels measured in none of these wells conclusively satisfied the wetland hydrology criteria.

Wetland hydrology: Yes: No: X
Rationale: Water level data collected from the seven wells at the site indicate that this site is not inundated or saturated for a sufficient duration to satisfy the wetland hydrology criterion.

DETERMINATION AND RATIONALE:

Is the site a wetland? Yes: No: X
Rationale: Although dominant hydrophytic vegetation is present at the site, hydric soils and wetland hydrology are lacking; thus, we determined that this site is not a wetland. The NWI did not code this site as a wetland.

ROUTINE ONSITE WETLAND DETERMINATION

Site 1 (page 5 of 5)

Field Investigators: Feist, Keene, Larimore, Wilm
Date: 9 September 1999  Project Name: FAP 310 (US 67)
Section No.: 104RS-2, (104)BR, (104-1)BR, 105RS-2
State: Illinois  County: Mercer  Applicant: IDOT District 4
Site Name: Wetland creation
Legal Description: NE 1/4, SW 1/4, Sec. 35, T. 15 N., R. 2 W
Location: This wetland creation site is located 38.1 m (125 ft) south of the
Edwards River and 15.2 m (50 ft) east of US 67.

Determined by: Mary Ann Feist, Rick Larimore, and Brian Wilm
(vegetation and hydrology)
Dennis Keene
(soils and hydrology)
Illinois Natural History Survey
607 East Peabody Drive
Champaign, Illinois 61820
(217)244-6858 (Feist)

Champaign, Illinois 61820
ROUTINE ONSITE WETLAND DETERMINATION
Site 2 (page 1 of 4)

Field Investigators: Feist, Keene, Larimore, Wilm
Date: 9 September 1999  Project Name: FAP 310 (US 67)
Section No.: 104RS-2, (104)BR, (104-1)BR, 105RS-2
State: Illinois  County: Mercer  Applicant: IDOT District 4
Site Name: Wetland restoration
Legal Description: SE 1/4, NW 1/4, Sec. 35, T. 15 N., R. 2 W
Location: This wetland restoration site is located just north of the Edwards River and just east of US 67.

Do normal environmental conditions exist at this site?  Yes: X  No:
Has the vegetation, soils, or hydrology been significantly disturbed? Yes:  No: X

VEGETATION
Dominant Plant Species  Indicator Status  Stratum
1. Ambrosia trifida  FAC+  herb
2. Echinochloa muricata  OBL  herb
3. Panicum dichotomiflorum  FACW+  herb
4. Polygonum pensylvanicum  FACW+  herb
5. Setaria glauca  FAC  herb

Percentage of dominant species that are OBL, FACW, FAC+, or FAC: 100%

Hydrophytic vegetation: Yes: X  No:
Rationale: Less than 50% of the dominants are OBL, FACW, FAC+, or FAC.

SOILS
Series and phase: Undetermined
On Mercer County hydric soils list?  Yes:  No: X
Is the soil a histosol? Yes:  No: X  Histic epipedon present? Yes:  No: X
Redox concentrations: Yes:  No:  Undet: X
Redox depletions: Yes:  No:  Undet: X
Matrix color: NA
Other indicators: None

Hydric soils: Yes:  No:  Undet: X
Rationale: This soil has been altered because of cut and fill activities used in building the road and bridge. The site was severely compacted and contained rock and gravel. Penetration of the soil surface was nearly impossible. Soil colors of this material would not reflect the true soil genesis at this site.
ROUTINE ONSITE WETLAND DETERMINATION
Site 2 (page 2 of 4)

Field Investigators: Feist, Keene, Larimore, Wilm
Date: 9 September 1999 Project Name: FAP 310 (US 67)
Section No.: 104RS-2, (104)BR, (104-1)BR, 105RS-2
State: Illinois County: Mercer Applicant: IDOT District 4
Site Name: Wetland restoration
Legal Description: SE 1/4, NW 1/4, Sec. 35, T. 15 N., R. 2 W
Location: This wetland restoration site is located just north of the Edwards River and just east of US 67.

HYDROLOGY
Inundated: Yes: No: X Depth of standing water: NA
Depth to saturated soil: NA
Overview of hydrological flow through the system: This site is hydrologically influenced by precipitation and overflow from the Edwards River. Water leaves the site via evapotranspiration and sheet flow into the adjacent Edwards River.
Size of Watershed: 699 km² (270 mi²)
Other field evidence observed: None

Wetland hydrology: Yes: No: Undetermined: X
Rationale: No indicators of wetland hydrology were observed, however, this site was disturbed within the last year by construction activities and tree plantings. The position of this site between the Edwards River and a levee, suggests that the area floods for some period of time each year. At this time, it is uncertain as to whether this site is inundated or saturated for a sufficient duration to satisfy the wetland hydrology criterion.

DETERMINATION AND RATIONALE:

Is the site a wetland? Yes: No: X
Rationale: Although dominant hydrophytic vegetation is present at the site, hydric soils and wetland hydrology are lacking or undetermined at this time; thus, we determined that this site is currently not a wetland. The NWI coded this site as a temporarily flooded, broad-leaved deciduous, forested, palustrine wetland (PFO1A).
